

Early Journal Content on JSTOR, Free to Anyone in the World

This article is one of nearly 500,000 scholarly works digitized and made freely available to everyone in the world by JSTOR.

Known as the Early Journal Content, this set of works include research articles, news, letters, and other writings published in more than 200 of the oldest leading academic journals. The works date from the mid-seventeenth to the early twentieth centuries.

We encourage people to read and share the Early Journal Content openly and to tell others that this resource exists. People may post this content online or redistribute in any way for non-commercial purposes.

JSTOR is a digital library of academic journals, books, and primary source objects. JSTOR helps people discover, use, and build upon a wide range of content through a powerful research and teaching platform, and preserves this content for future generations. JSTOR is part of ITHAKA, a not-for-profit organization that also includes Ithaka S+R and Portico. For more information about JSTOR, please contact support@jstor.org.

of yeast cells. When possible they used the potassium permanganate titration method for determining catalase activity. In cases where additions of thymol, glucose, etc., rendered the permanganate method inaccurate, the volumetric method was used. They used mainly their cultures of distillery top yeast S.B. II. Some experiments were run with brewery bottom yeast. They agree with PHRAGMEN's findings that yeast splits dilute solutions of hydrogen peroxide without secreting a soluble enzyme into the bathing fluid. The reaction is one of the first order. The reaction constant increases in proportion to the amount of yeast. Small amounts of protoplasmic poisons (toluol or chloroform) raise the catalase activity of these cells 6-fold. When cells were dried in the air or otherwise without injuring them, the catalase activity rose 10-15-fold. When emulsions of the yeast were heated 0.5-2 hours at 55-63° C., the catalase activity rose 20-30-fold. The activation by heating is greatly influenced by reagents in the emulsion at the time of heating. Similar activation of catalase has been demonstrated in a number of other micro-organisms. The catalase activity of yeast can be raised by previous treatment with sugar solutions. This increased catalase activity is not due to increased permeability of the cells to catalase, but is an activation within the living cells. The reaction constant is not a measure for the catalase content of the cells.—WM. CROCKER.

Parasitism.—HAWKINS and HARVEY¹⁵ have made an interesting study of the nature of the resistance of White McCormick tubers to the tuber rot caused by *Pythium debaryanum* Hesse. The White McCormick is very resistant to the disease, while Bliss, Triumph, and Green Mountain are very susceptible. From their experiments they think it probable that the fungus enters the cells of the potato by mechanical puncture of the cell walls and not by enzyme action. The McCormick is less susceptible to the disease than the other varieties, because its cell walls are more resistant to this mechanical puncture. Determinations of the pressure required to puncture the cell walls give much higher results for the McCormick than for the susceptible varieties. The rate of growth of the fungus is much slower in the McCormick. Correlated with the greater resistance of the McCormick is a higher crude fiber content. If its osmotic pressure is to be considered the force available to the fungus for this mechanical puncture of the cell walls, then the cases of resistance of the potatoes used in the experiments would be explained, with three exceptions.—S. V. EATON.

Correlations.—CHILD and BELLAMY¹⁶ have done a very interesting piece of work on correlations in plants. They can break up correlation effects by

¹⁵ HAWKINS, L. A., and HARVEY, R. B., Physiological study of the parasitism of *Pythium debaryanum* Hesse on the potato tuber. Jour. Agric. Res. 18:275-297. pls. 35-37. figs. 2. 1919.

cooling 2-3 cm. zones of petioles and stems to a temperature of $2.5-3^{\circ}\text{C}$. In *Bryophyllum*, when such zones of the petiole are cooled, the broken correlation is manifested by development, not only in the notches of the leaf treated, but by development in the notches of the opposite leaf, as well as leaves both up and down the stem. The effect extends farther in the basal direction than in the apical. This indicates marked complexity in the correlation inhibitive effects. In *Phaseolus* the axial buds below the cooled zone grew. In *Saxifraga sarmientosa* the runner tip could be thus isolated. All of these results favor MCCALLUM's view that correlative effects are brought about by conduction of stimuli, mainly inhibitory stimuli, and not by movements of materials.—WM. CROCKER.

Fermentation.—EULER and SVANBERG¹⁷ made a study of alcoholic fermentation in an alkaline medium in which $P_H=8$. Top yeast and *Torula* gave about equal weights of carbon dioxide and alcohol, each equal to 30-33d of the weight of the sugar fermented. Glucose, fructose, and invert sugar were fermented with about equal speed, mannose about 30 per cent as fast, and galactose very slowly. Invertase is active in this medium and maltase inactive. The following are the maximum alkalinities in which cell division occurs in the various yeasts: Froberg Unterhefe B., $P_H=7.7-8$; Brennerei Oberhefe S.B. II, $P_H=7.3-8.4$; *Sacch. ellipsoideus*, $P_H=7.9$; *Pseudosacch. apiculatus*, $P_H=7.6$. Increase in weight occurred in S.B. up to $P_H=8.5$. For Froberg Unterhefe H the full curve of acid sensitivity was worked out and the optimum was found to be at $P_H=5$.—WM. CROCKER.

Exudation of water by leaves.—Miss FLOOD¹⁸ has recently investigated the exudation of extremely pure water by the leaf tips of *Colocasia antiquorum*. Examination of sections of leaf tips showed no membrane, or other structure which might act as a filter, between the vascular system of the leaf blade and the pores leading to the tip. Solutions of India ink, gelatine, and starch were forced through the vascular system and exuded at the tips. Exudation from leaves attached to the plant continued at the normal rate when leaf tips were anaesthetized. Miss FLOOD is of the opinion that cells lower down in the plant are responsible for the secretion and filtration of water, but finds no evidence for the existence of such cells except in the root.—J. M. ARTHUR.

Colorado grasslands.—Reviewing the investigations of the grasslands of Colorado by himself and others, RAMALEY¹⁹ enumerates all the associations
